Lecture 16: Applications of Subgame Perfect Nash Equilibrium

Ultimatum Game

Alternating offers

Stackelberg Competition

Ultimatum Game

Alternating offers

Stackelberg Competition

1. Player 1 makes a proposal $(x, 1000 - x)$ of how to split 100 pesos among $(100, 900), \dots, (800, 200), (900, 100)$

2. Player 2 accepts or rejects the proposal

3. If player 2 rejects both obtain 0. If 2 accepts, then the payoffs or the two players are determined by $(x, 1000 - x)$

- In any pure strategy SPNE, player 2 accepts all offers

- In any pure strategy SPNE, player 2 accepts all offers

- In any SPNE, player 1 makes the proposal $(900, 100)$

- This is far from what happens in reality

- This is far from what happens in reality

- When extreme offers like $(900, 100)$ are made, player 2 rejects in many cases

- This is far from what happens in reality

- When extreme offers like $(900, 100)$ are made, player 2 rejects in many cases

- Player 2 may care about inequality or positive utility associated with "punishment" aversion

Ultimatum Game

Alternating offers

Stackelberg Competition

- Two players are deciding how to split a pie of size 1

- Two players are deciding how to split a pie of size 1
- The players would rather get an agreement today than tomorrow (i.e., discount factor)

- Player 1 makes an offer θ_1

- Player 1 makes an offer θ_1
- Player 2 accepts or rejects the proposal

- Player 1 makes an offer θ_1
- Player 2 accepts or rejects the proposal
- If player 2 rejects, player 2 makes an offer θ_2

- Player 1 makes an offer θ_1
- Player 2 accepts or rejects the proposal
- If player 2 rejects, player 2 makes an offer θ_2
- If player 1 accepts or rejects the proposal

- Player 1 makes an offer θ_1
- Player 2 accepts or rejects the proposal
- If player 2 rejects, player 2 makes an offer θ_2
- If player 1 accepts or rejects the proposal
- If player 1 rejects, player 1 makes an offer θ_3

- Player 1 makes an offer θ_1
- Player 2 accepts or rejects the proposal
- If player 2 rejects, player 2 makes an offer θ_2
- If player 1 accepts or rejects the proposal
- If player 1 rejects, player 1 makes an offer θ_3
- ... and on and on for T periods

- Player 1 makes an offer θ_1
- Player 2 accepts or rejects the proposal
- If player 2 rejects, player 2 makes an offer θ_2
- If player 1 accepts or rejects the proposal
- If player 1 rejects, player 1 makes an offer θ_3
- ... and on and on for T periods
- If no offer is ever accepted, both payoffs equal zero

The discount factor is $\delta \leq 1$.
If Player 1 offer is accepted by Player 2 in round m,

$$\pi_1 = \delta^m \theta_m,$$

$$\pi_2 = \delta^m (1 - \theta_m).$$

If Player 2 offer is accepted, reverse the subscripts

- Consider first the game without discounting

- Consider first the game without discounting
- There is a unique SPNE:

- Consider first the game without discounting
- There is a unique SPNE:

- Consider first the game without discounting
- There is a unique SPNE: The player that makes the last offer gets the whole pie
- Last-mover advantage

- In the game with discounting, the total value of the pie is 1 in the first period, δ in the second, and so forth

- In the game with discounting, the total value of the pie is 1 in the first period, δ in the second, and so forth
- Assume Player 1 makes the last offer

- In the game with discounting, the total value of the pie is 1 in the first period, δ in the second, and so forth
- Assume Player 1 makes the last offer
- In period T, if it is reached, Player 1 would offer 0 to Player 2

- In the game with discounting, the total value of the pie is 1 in the first period, δ in the second, and so forth
- Assume Player 1 makes the last offer
- In period T, if it is reached, Player 1 would offer 0 to Player 2
- Player 2 would accept (indifferent between accepting and rejecting)

- In the game with discounting, the total value of the pie is 1 in the first period, δ in the second, and so forth
- Assume Player 1 makes the last offer
- In period T, if it is reached, Player 1 would offer 0 to Player 2
- Player 2 would accept (indifferent between accepting and rejecting)
- In period $(T-1)$, Player 2 could offer Smith δ, keeping $(1-\delta)$ for himself

- In the game with discounting, the total value of the pie is 1 in the first period, δ in the second, and so forth
- Assume Player 1 makes the last offer
- In period T, if it is reached, Player 1 would offer 0 to Player 2
- Player 2 would accept (indifferent between accepting and rejecting)
- In period $(T-1)$, Player 2 could offer Smith δ, keeping $(1-\delta)$ for himself
- Player 1 would accept (indifferent between accepting and rejecting) since the **whole pie** in the next period is worth δ

- In period $(T-2)$, Player 1 would offer Player 2 $\delta(1-\delta)$, keeping $(1-\delta(1-\delta))$ for himself

- In period $(T-2)$, Player 1 would offer Player 2 $\delta(1-\delta)$, keeping $(1-\delta(1-\delta))$ for himself
- Player 2 would accept since he can earn $(1-\delta)$ in the next period, which is worth $\delta(1-\delta)$ today

- In period $(T-2)$, Player 1 would offer Player 2 $\delta(1-\delta)$, keeping $(1-\delta(1-\delta))$ for himself
- Player 2 would accept since he can earn $(1-\delta)$ in the next period, which is worth $\delta(1-\delta)$ today
- In period $(T-3)$, Player 2 would offer Player 1 $\delta[1-\delta(1-\delta)]$, keeping $(1-\delta[1-\delta(1-\delta)])$ for himself

- In period $(T-2)$, Player 1 would offer Player 2 $\delta(1-\delta)$, keeping $(1-\delta(1-\delta))$ for himself
- Player 2 would accept since he can earn $(1-\delta)$ in the next period, which is worth $\delta(1-\delta)$ today
- In period $(T-3)$, Player 2 would offer Player 1 $\delta[1-\delta(1-\delta)]$, keeping $(1-\delta[1-\delta(1-\delta)])$ for himself
- Player 1 would accept...

- In period $(T-2)$, Player 1 would offer Player 2 $\delta(1-\delta)$, keeping $(1-\delta(1-\delta))$ for himself
- Player 2 would accept since he can earn $(1-\delta)$ in the next period, which is worth $\delta(1-\delta)$ today
- In period $(T-3)$, Player 2 would offer Player 1 $\delta[1-\delta(1-\delta)]$, keeping $(1-\delta[1-\delta(1-\delta)])$ for himself
- Player 1 would accept...
- ...

- In period $(T-2)$, Player 1 would offer Player 2 $\delta(1-\delta)$, keeping $(1-\delta(1-\delta))$ for himself
- Player 2 would accept since he can earn $(1-\delta)$ in the next period, which is worth $\delta(1-\delta)$ today
- In period $(T-3)$, Player 2 would offer Player 1 $\delta[1-\delta(1-\delta)]$, keeping $(1-\delta[1-\delta(1-\delta)])$ for himself
- Player 1 would accept...
- ...
- In equilibrium, the very first offer would be accepted, since it is chosen precisely so that the other player can do no better by waiting

Table 1 shows the progression of Player 1's shares when $\delta = 0.9$.

Table 1: Alternating Offers over Finite Time

Round	1's share	2's share	Total value	Who offers?
$T-3$	$\delta(1-\delta(1-\delta))$	$1-\delta(1-\delta(1-\delta))$	δ^{T-4}	2
$T-2$	$1-\delta(1-\delta)$	$\delta(1-\delta)$	δ^{T-3}	1
$T-1$	δ	$1-\delta$	δ^{T-2}	2
T	1	0	δ^{T-1}	1

- If $T = 3$ (i.e, 1 offers, 2 offers, 1 offers)

- If $T = 3$ (i.e, 1 offers, 2 offers, 1 offers)

- One offers $\delta(1-\delta)$, 2 accepts in period 1

- Player 1 always does a little better when he makes the offer than when Player 2 does

- Player 1 always does a little better when he makes the offer than when Player 2 does

- If we consider just the class of periods in which Player 1 makes the offer, Player 1's share falls

Stackelberg Competition

- Recall back to the model of Cournot duopoly, where two firms set quantities

- Recall back to the model of Cournot duopoly, where two firms set quantities

- Suppose instead that the firms move in sequence which is called a **Stackelberg competition game**

- Recall back to the model of Cournot duopoly, where two firms set quantities
- Suppose instead that the firms move in sequence which is called a **Stackelberg competition game**
- Suppose that the inverse demand function is given by:

$$P(q_1 + q_2).$$

- Recall back to the model of Cournot duopoly, where two firms set quantities
- Suppose instead that the firms move in sequence which is called a **Stackelberg competition game**
- Suppose that the inverse demand function is given by:

$$P(q_1 + q_2).$$

- Firms have the cost functions $c_i(q_i)$.

Te timing of the game is given by:

1. First Firm 1 chooses $q_1 \geq 0$

2. Second Firm 2 observes the chosen q_1 and then chooses q_2

- The game tree in this game is then depicted by an infinite tree

- Let us write down the normal form representation of this game.

- Let us write down the normal form representation of this game.

- A pure strategy for firm 1 is just a choice of $q_1 \geq 0$

- Let us write down the normal form representation of this game.
- A pure strategy for firm 1 is just a choice of $q_1 \geq 0$
- A strategy for firm 2 specifies what it does after every choice of q_1

- Let us write down the normal form representation of this game.
- A pure strategy for firm 1 is just a choice of $q_1 \geq 0$
- A strategy for firm 2 specifies what it does after every choice of q_1
- Firm 2's strategy is a function $q_2(q_1)$ which specifies exactly what firm 2 does if q_1 is the chosen strategy of player 1

The utility functions for firm i when firm 1 chooses q_1 and firm 2 chooses the strategy (or function) $q_2(\cdot)$ is given by:

$$\pi_1(q_1, q_2(\cdot)) = P(q_1 + q_2(q_1))q_1 - c_1(q_1)$$
$$\pi_2(q_1, q_2(\cdot)) = P(q_1 + q_2(q_1))q_2(q_1) - c_2(q_2(q_1))$$

- There are many Nash equilibria of this game which are a bit counterintuitive

- There are many Nash equilibria of this game which are a bit counterintuitive
- Cconsider the following specific game with demand function given by:

$$P(q_1 + q_2) = A - q_1 - q_2.$$

- There are many Nash equilibria of this game which are a bit counterintuitive

- Cconsider the following specific game with demand function given by:

$$P(q_1 + q_2) = A - q_1 - q_2.$$

- Let the marginal costs of both firms be zero

- There are many Nash equilibria of this game which are a bit counterintuitive

- Cconsider the following specific game with demand function given by:

$$P(q_1 + q_2) = A - q_1 - q_2.$$

- Let the marginal costs of both firms be zero

- Then the normal form simplifies:

$$u_1(q_1, q_2(\cdot)) = (A - q_1 - q_2(q_1))q_1,$$
$$u_2(q_1, q_2(\cdot)) = (A - q_1 - q_2(q_1))q_2(q_1).$$

- What is an example of a Nash equilibrium of this game?

- What is an example of a Nash equilibrium of this game?

- Let $\alpha \in [0, A)$ and consider the following strategy profile:

$$q_1^* = \alpha, q_2^*(q_1) = \begin{cases} A & \text{if } q_1 \neq \alpha, \\ \frac{A-\alpha}{2} & \text{if } q_1 = \alpha. \end{cases}$$

- What is an example of a Nash equilibrium of this game?
- Let $\alpha \in [0, A)$ and consider the following strategy profile:

$$q_1^* = \alpha, q_2^*(q_1) = \begin{cases} A & \text{if } q_1 \neq \alpha, \\ \frac{A-\alpha}{2} & \text{if } q_1 = \alpha. \end{cases}$$

- Let us check that indeed this constitutes a Nash equilibrium

- First we check the best response of player 1

- First we check the best response of player 1

- If player 2 plays q_2^*, then player 1's utility function is given by:

$$u_1(q_1, q_2^*(\cdot)) = \begin{cases} \left(A - \alpha - \left(\frac{A-\alpha}{2}\right)\right)\alpha > 0 & \text{if } q_1 = \alpha \\ -q_1^2 \leq 0 & \text{if } q_1 \neq \alpha. \end{cases}$$

- First we check the best response of player 1
- If player 2 plays q_2^*, then player 1's utility function is given by:

$$u_1(q_1, q_2^*(\cdot)) = \begin{cases} \left(A - \alpha - \left(\frac{A-\alpha}{2}\right)\right)\alpha > 0 & \text{if } q_1 = \alpha \\ -q_1^2 \leq 0 & \text{if } q_1 \neq \alpha. \end{cases}$$

- Thus,

$$\max_{q_1 \geq 0} u_1(q_1, q_2^*(\cdot))$$

is solved at $q_1^* = \alpha$

- First we check the best response of player 1
- If player 2 plays q_2^*, then player 1's utility function is given by:

$$u_1(q_1, q_2^*(\cdot)) = \begin{cases} \left(A - \alpha - \left(\frac{A-\alpha}{2}\right)\right)\alpha > 0 & \text{if } q_1 = \alpha \\ -q_1^2 \leq 0 & \text{if } q_1 \neq \alpha. \end{cases}$$

- Thus,

$$\max_{q_1 \geq 0} u_1(q_1, q_2^*(\cdot))$$

is solved at $q_1^* = \alpha$

- Firm 1 is best responding to player 2's strategy.

- Suppose that firm 1 plays the strategy q_1^*. Is firm 2 best responding?

- Suppose that firm 1 plays the strategy q_1^*. Is firm 2 best responding?
- Firm 2's utility function is given by:

$$u_2(q_1^*, q_2(\cdot)) = (A - \alpha - q_2(\alpha))q_2(\alpha).$$

- Suppose that firm 1 plays the strategy q_1^*. Is firm 2 best responding?
- Firm 2's utility function is given by:

$$u_2(q_1^*, q_2(\cdot)) = (A - \alpha - q_2(\alpha))q_2(\alpha).$$

- Thus, firm 2 wants to choose the optimal strategy $q_2(\cdot)$ that maximizes the following utility:

$$\max_{q_2(\cdot)} (A - \alpha - q_2(\alpha))q_2(\alpha)$$

- Suppose that firm 1 plays the strategy q_1^*. Is firm 2 best responding?
- Firm 2's utility function is given by:

$$u_2(q_1^*, q_2(\cdot)) = (A - \alpha - q_2(\alpha))q_2(\alpha).$$

- Thus, firm 2 wants to choose the optimal strategy $q_2(\cdot)$ that maximizes the following utility:

$$\max_{q_2(\cdot)}(A - \alpha - q_2(\alpha))q_2(\alpha)$$

- By the first order condition, we know that

$$q_2(\alpha) = \frac{A - \alpha}{2}.$$

- Suppose that firm 1 plays the strategy q_1^*. Is firm 2 best responding?
- Firm 2's utility function is given by:

$$u_2(q_1^*, q_2(\cdot)) = (A - \alpha - q_2(\alpha))q_2(\alpha).$$

- Thus, firm 2 wants to choose the optimal strategy $q_2(\cdot)$ that maximizes the following utility:

$$\max_{q_2(\cdot)} (A - \alpha - q_2(\alpha))q_2(\alpha)$$

- By the first order condition, we know that

$$q_2(\alpha) = \frac{A - \alpha}{2}.$$

- The utility function of firm 2 does not depend at all on what it chooses for $q_2^*(q_1)$ when $q_1 \neq \alpha$

- Suppose that firm 1 plays the strategy q_1^*. Is firm 2 best responding?
- Firm 2's utility function is given by:

$$u_2(q_1^*, q_2(\cdot)) = (A - \alpha - q_2(\alpha))q_2(\alpha).$$

- Thus, firm 2 wants to choose the optimal strategy $q_2(\cdot)$ that maximizes the following utility:

$$\max_{q_2(\cdot)}(A - \alpha - q_2(\alpha))q_2(\alpha)$$

- By the first order condition, we know that

$$q_2(\alpha) = \frac{A - \alpha}{2}.$$

- The utility function of firm 2 does not depend at all on what it chooses for $q_2^*(q_1)$ when $q_1 \neq \alpha$
- In particular, q_2^* is a best response for firm 2

- The above observation allows us to conclude that there are many Nash equilibria of this game

- The above observation allows us to conclude that there are many Nash equilibria of this game
- In fact there are many more than the ones above

- The above observation allows us to conclude that there are many Nash equilibria of this game
- In fact there are many more than the ones above
- The Nash equilibria highlighted above all lead to different predictions

- The above observation allows us to conclude that there are many Nash equilibria of this game
- In fact there are many more than the ones above
- The Nash equilibria highlighted above all lead to different predictions
- The equilibrium outcome of the above Nash equilibrium above is that firm 1 sets the price α and firm 2 sets the price $(A-\alpha)/2$.

- The above observation allows us to conclude that there are many Nash equilibria of this game
- In fact there are many more than the ones above
- The Nash equilibria highlighted above all lead to different predictions
- The equilibrium outcome of the above Nash equilibrium above is that firm 1 sets the price α and firm 2 sets the price $(A - \alpha)/2$.
- In particular, in the Nash equilibrium corresponding to $\alpha = 0$, the equilibrium outcome is for firm 1 to choose a quantity of 0 and firm 2 setting a price of $A/2$

- The above observation allows us to conclude that there are many Nash equilibria of this game
- In fact there are many more than the ones above
- The Nash equilibria highlighted above all lead to different predictions
- The equilibrium outcome of the above Nash equilibrium above is that firm 1 sets the price α and firm 2 sets the price $(A-\alpha)/2$.
- In particular, in the Nash equilibrium corresponding to $\alpha = 0$, the equilibrium outcome is for firm 1 to choose a quantity of 0 and firm 2 setting a price of $A/2$
- This would be the same outcome if firm 2 were the monopolist in this market

- Consider the equilibrium in which $\alpha = 0$

- Consider the equilibrium in which $\alpha = 0$
- This equilibrium is highly counterintuitive because firm 2 obtains monopoly profits

- Consider the equilibrium in which $\alpha = 0$
- This equilibrium is highly counterintuitive because firm 2 obtains monopoly profits
- The reason is that essentially firm 2 is playing a strategy that involves **non-credible threats**

- Consider the equilibrium in which $\alpha = 0$
- This equilibrium is highly counterintuitive because firm 2 obtains monopoly profits
- The reason is that essentially firm 2 is playing a strategy that involves **non-credible threats**
- Firm 2 is threatening to overproduce if firm 1 produces anything at all

- Consider the equilibrium in which $\alpha = 0$
- This equilibrium is highly counterintuitive because firm 2 obtains monopoly profits
- The reason is that essentially firm 2 is playing a strategy that involves **non-credible threats**
- Firm 2 is threatening to overproduce if firm 1 produces anything at all
- As a result, the best that firm 1 can do is to produce nothing

- Consider the equilibrium in which $\alpha = 0$
- This equilibrium is highly counterintuitive because firm 2 obtains monopoly profits
- The reason is that essentially firm 2 is playing a strategy that involves **non-credible threats**
- Firm 2 is threatening to overproduce if firm 1 produces anything at all
- As a result, the best that firm 1 can do is to produce nothing
- If firm 1 were to hypothetically choose $q_1 > 0$, then firm 2 would obtain negative profits if it indeed follows through with $q_2^*(q_1)$.

- Many Nash equilibria are counterintuitive in the Stackelberg game

- Many Nash equilibria are counterintuitive in the Stackelberg game

- To eliminate such counterintuitive equilibria, we focus instead on SPNE instead of NE

- Many Nash equilibria are counterintuitive in the Stackelberg game

- To eliminate such counterintuitive equilibria, we focus instead on SPNE instead of NE

- Lets continue with the setting in which marginal costs are zero and the demand function is given by $A - q_1 - q_2$

- We always start with the smallest/last subgames which correspond to the decisions of firm 2 after firm 1's choice of q_1 has been made

- We always start with the smallest/last subgames which correspond to the decisions of firm 2 after firm 1's choice of q_1 has been made

- The utility function of firm 2 is given by:

$$u_2(q_1, q_2(\cdot)) = (A - q_1 - q_2(q_1))q_2(q_1).$$

- We always start with the smallest/last subgames which correspond to the decisions of firm 2 after firm 1's choice of q_1 has been made

- The utility function of firm 2 is given by:

$$u_2(q_1, q_2(\cdot)) = (A - q_1 - q_2(q_1))q_2(q_1).$$

- So, player 2 solves:

$$\max_{q_2(\cdot)}(A - q_1 - q_2(q_1))q_2(q_1).$$

- **Case 1:** $q_1 > A$

- **Case 1:** $q_1 > A$
- In this case, the best response of firm 2 is to set a quantity $q_2^*(q_1) = 0$ since producing at all gives negative profits.

- **Case 1:** $q_1 > A$

- In this case, the best response of firm 2 is to set a quantity $q_2^*(q_1) = 0$ since producing at all gives negative profits.

- **Case 2:** $q_1 \leq A$

- **Case 1:** $q_1 > A$
- In this case, the best response of firm 2 is to set a quantity $q_2^*(q_1) = 0$ since producing at all gives negative profits.
- **Case 2:** $q_1 \leq A$
- In this case, the first order condition implies:

$$q_2^*(q_1) = \frac{A - q_1}{2}.$$

- Thus, in any SPNE, player 2 must play the following strategy:

$$q_2^*(q_1) = \begin{cases} \frac{A-q_1}{2} & \text{if } q_1 \leq A \\ 0 & \text{if } q_1 > A. \end{cases}$$

- Then player 1's utility function given that player 2 plays q_2^* is given by:

$$u_1(q_1, q_2^*(\cdot)) = q_1(A - q_1 - q_2^*(q_1)) = \begin{cases} q_1(A - q_1) & \text{if } q_1 > A, \\ q_1 \frac{A - q_1}{2} & \text{if } q_1 \leq A. \end{cases}$$

- Then player 1's utility function given that player 2 plays q_2^* is given by:

$$u_1(q_1, q_2^*(\cdot)) = q_1(A - q_1 - q_2^*(q_1)) = \begin{cases} q_1(A - q_1) & \text{if } q_1 > A, \\ q_1 \frac{A - q_1}{2} & \text{if } q_1 \leq A. \end{cases}$$

- Thus, firm 1 maximizes $\max_{q_1} u_1(q_1, q_2^*(\cdot))$

- Then player 1's utility function given that player 2 plays q_2^* is given by:

$$u_1(q_1, q_2^*(\cdot)) = q_1(A - q_1 - q_2^*(q_1)) = \begin{cases} q_1(A - q_1) & \text{if } q_1 > A, \\ q_1 \frac{A - q_1}{2} & \text{if } q_1 \leq A. \end{cases}$$

- Thus, firm 1 maximizes $\max_{q_1} u_1(q_1, q_2^*(\cdot))$

- Firm 1 will never choose $q_1 > A$ since then it obtains negative profits

- Then player 1's utility function given that player 2 plays q_2^* is given by:

$$u_1(q_1, q_2^*(\cdot)) = q_1(A - q_1 - q_2^*(q_1)) = \begin{cases} q_1(A - q_1) & \text{if } q_1 > A, \\ q_1 \frac{A - q_1}{2} & \text{if } q_1 \leq A. \end{cases}$$

- Thus, firm 1 maximizes $\max_{q_1} u_1(q_1, q_2^*(\cdot))$
- Firm 1 will never choose $q_1 > A$ since then it obtains negative profits
- Thus, firm 1 maximizes:

$$\max_{q_1 \in [0,A]} q_1 \frac{A - q_1}{2}.$$

- The first order condition for this problem is given by:

$$q_1^* = \frac{A}{2}$$

- The first order condition for this problem is given by:

$$q_1^* = \frac{A}{2}$$

- The SPNE of the Stackelberg game is given by:

$$\left(q_1^* = \frac{A}{2}, q_2^*(q_1) = \frac{A - q_1}{2} \right)$$

- The first order condition for this problem is given by:

$$q_1^* = \frac{A}{2}$$

- The SPNE of the Stackelberg game is given by:

$$\left(q_1^* = \frac{A}{2}, q_2^*(q_1) = \frac{A - q_1}{2} \right)$$

- The **equilibrium outcome** is for firm 1 to choose $A/2$ and firm 2 to choose $A/4$

- The Cournot game was one in which all firms chose quantities simultaneously

- The Cournot game was one in which all firms chose quantities simultaneously
- In that game, since there is only one subgame, SPNE was the same as the set of NE

- The Cournot game was one in which all firms chose quantities simultaneously
- In that game, since there is only one subgame, SPNE was the same as the set of NE
- Lets solve for the set of SPNE (which is the same as NE) in the Cournot game with the same demand function and same costs

- The Cournot game was one in which all firms chose quantities simultaneously
- In that game, since there is only one subgame, SPNE was the same as the set of NE
- Lets solve for the set of SPNE (which is the same as NE) in the Cournot game with the same demand function and same costs
- In this case, (q_1^*, q_2^*) is a NE if and only if

$$q_1^* \in BR_1(q_2^*), q_2^* \in BR_2(q_1^*).$$

- For $q_1^* \in BR_1(q_2^*)$, we need q_1^* to solve the following maximization problem:

$$\max_{q_1 \geq 0} (A - q_1 - q_2^*) q_1.$$

- For $q_1^* \in BR_1(q_2^*)$, we need q_1^* to solve the following maximization problem:

$$\max_{q_1 \geq 0} (A - q_1 - q_2^*) q_1.$$

- By the FOC, we have:

$$q_1^* = \frac{A - q_2^*}{2}.$$

- For $q_1^* \in BR_1(q_2^*)$, we need q_1^* to solve the following maximization problem:

$$\max_{q_1 \geq 0} (A - q_1 - q_2^*) q_1.$$

- By the FOC, we have:

$$q_1^* = \frac{A - q_2^*}{2}.$$

- Similarly for $q_2^* \in BR_2(q_1^*)$,

$$q_2^* = \frac{A - q_1^*}{2}.$$

- For $q_1^* \in BR_1(q_2^*)$, we need q_1^* to solve the following maximization problem:

$$\max_{q_1 \geq 0} (A - q_1 - q_2^*) q_1.$$

- By the FOC, we have:

$$q_1^* = \frac{A - q_2^*}{2}.$$

- Similarly for $q_2^* \in BR_2(q_1^*)$,

$$q_2^* = \frac{A - q_1^*}{2}.$$

- As a result, solving these two equations, we get:

$$q_1^* = q_2^* = \frac{A}{3}.$$

In the Cournot game, note that firms' payoffs are:

$$\pi_1^c = \frac{A^2}{9}, \pi_2^c = \frac{A^2}{9}.$$

As we already saw, this was not Pareto efficient since each firm is getting a payoff that is strictly less than 1/2 of the monopoly profits.

- In the Stackelberg competition game, the total quantity supplied is $\frac{3}{4}A$

- In the Stackelberg competition game, the total quantity supplied is $\frac{3}{4}A$

- Thus, the firms' payoffs in the SPNE is:

$$\pi_1^s = \frac{1}{4}A \cdot \frac{A}{2} = \frac{A^2}{8}, \pi_2^s = \frac{1}{4}A \cdot \frac{A}{4} = \frac{A^2}{16}.$$

- In the Stackelberg competition game, the total quantity supplied is $\frac{3}{4}A$

- Thus, the firms' payoffs in the SPNE is:

$$\pi_1^s = \frac{1}{4}A \cdot \frac{A}{2} = \frac{A^2}{8}, \pi_2^s = \frac{1}{4}A \cdot \frac{A}{4} = \frac{A^2}{16}.$$

- Firm 1 obtains a better payoff than firm 2

- In the Stackelberg competition game, the total quantity supplied is $\frac{3}{4}A$
- Thus, the firms' payoffs in the SPNE is:

$$\pi_1^s = \frac{1}{4}A \cdot \frac{A}{2} = \frac{A^2}{8}, \pi_2^s = \frac{1}{4}A \cdot \frac{A}{4} = \frac{A^2}{16}.$$

- Firm 1 obtains a better payoff than firm 2
- This is intuitive since firm 1 always has the option of choosing the Cournot quantity $q_1 = A/3$, in which case firm 2 will indeed choose $q_2^*(q_1) = A/3$ giving a payoff of $A^2/9$

- In the Stackelberg competition game, the total quantity supplied is $\frac{3}{4}A$
- Thus, the firms' payoffs in the SPNE is:

$$\pi_1^s = \frac{1}{4}A \cdot \frac{A}{2} = \frac{A^2}{8}, \pi_2^s = \frac{1}{4}A \cdot \frac{A}{4} = \frac{A^2}{16}.$$

- Firm 1 obtains a better payoff than firm 2
- This is intuitive since firm 1 always has the option of choosing the Cournot quantity $q_1 = A/3$, in which case firm 2 will indeed choose $q_2^*(q_1) = A/3$ giving a payoff of $A^2/9$
- But by choosing something optimal, firm 1 will be able to do even better
